SEASON 9 - SECOND ROUND

Three friends live in a country with N cities, connected by $\mathrm{N}-1$ two-way roads. Naturally, any city can be reached by any other. Travelling through a road costs a certain amount of money (after all, fuel is not free). The tree friends live in three different cities $\mathrm{A}, \mathrm{B}$ and C . They want to meet up. They want to choose a city D (which could happen to be one A,B or C), so that the sum of the costs for each of their trips to that city is as low as possible. Write a program that answers several queries ( $A, B, C$ ) and for each query outputs the optimal city $D$ and how much the friends have to pay to get there.

## Input

From the first line of the input file meeting.in the number of cities N is entered.
From the next N -1 lines $\mathrm{F}_{\mathrm{i}}, \mathrm{T}_{\mathrm{i}}, \mathrm{C}_{\mathrm{i}}$ are entered - a road between cities $\mathrm{F}_{\mathrm{i}}$, and $\mathrm{T}_{\mathrm{i}}$ and its cost Next the number of queries $Q$ is entered.
For each of the queries on a separate line the towns of the three friends $A, B$ and $C$ are entered.

## Output

In the output file meeting. out for each of the queries print two numbers $D$ and $S$ - the city with the lowest sum of the costs needed to get to it from $A, B$ and $C$ and the sum itself.

## Constraints

$1 \leq N \leq 100000$
$0 \leq F, T, A, B, C, D<N$
$1 \leq Q \leq 1000$

## Time limit: 1 second

Memory limit: $\mathbf{2 5 6}$ MB

SEASON 9 - SECOND ROUND

## Example

| Input <br> (meeting.in) | Output <br> (meeting.out) | Explanation |
| :---: | :---: | :---: |
| 8   <br> 0 1 10 <br> 0 2 13 <br> 2 5 27 <br> 2 3 5 <br> 2 4 8 <br> 3 6 4 <br> 3 7 1 <br> 2   <br> 3 4 5 <br> 1 0 7 | $\begin{array}{ll} \hline 2 & 40 \\ 0 & 29 \end{array}$ | For the first query: <br> Going from city 3, 4 and 5 to city 2 costs 5, 8 and 27 respectively. The sum is therefore $5+8+27=40$, which is the minimum possible. <br> For the second query: <br> Going from cities 1,0 and 7 to city 0 costs 10, 0 and 19 respectively. |
